## 1. Introduction

### > GOALS:

- Introduce a new capability to GMI to simulate atmospheric aerosol components nitrate and ammonium.

- Examine the impact of multiphase chemical mechanism and new aerosol components on air quality and climate change.

### > APPROACH:

- Implement new tracers (ammonia NH<sub>3</sub>g, ammonium NH<sub>4</sub>a, nitrate NO<sub>3</sub>a) in GMI, set up NH<sub>3</sub>g emissions, and determine parameters for scavenging and chemical processes.

- Implement a thermodynamic equilibrium model (RPMARES) from GEOS-CHEM for a SO<sub>4</sub>-NO<sub>3</sub>a-NH<sub>4</sub>a-H<sub>2</sub>O system to partition semi-volatile species, such as HNO<sub>3</sub>, between gas (i.e. HNO<sub>3</sub>g) and aerosol phases (NO<sub>3</sub>a).

- Implement HNO<sub>3</sub> heterogeneous reactions on dust and sea salt particles.

- Analyze one year simulation results (year 2006) after one year spin up. Evaluate model aerosol results with the ground station observations from CASTNET and EMEP.

- Understand the change of chemistry fields with and without inclusion of NO<sub>3</sub>a and NH<sub>4</sub>a, i.e. CoupleNO<sub>3</sub> versus CoupleNoNO<sub>3</sub>.

## 2. GMI and its new capability

- GMI is a global 3D CTM with a coupled gas-aerosol chemistry scheme for troposphere and stratosphere.
- Previous GMI aerosol components include sulfate, BC, OC, dust, and sea salt.
- In this work, we expand GMI by adding aerosols NH<sub>4</sub>a and NO<sub>3</sub>a.

### NH<sub>3</sub>g emission

Annual NH<sub>3</sub>g emissions in 2001: 47.9 Tg

GEIA inventory of Bouwman et al. [1997]: Domesticated animals, Fertilizers, Human bodies, Industry, Fossil Fuel, Ocean, Crop, Soils, Wild animals.

Seasonal variation: Exponential dependences on T [Aneja et al., [2000] for domesticated animals and soils and linearly to the number of daylight hours for crop and fertilizers [Park et al., 2004]

GFED2, Van der Werf et al. [2006]: Biomass burning  
Yevich and Logan [2003]: Biofuel

Emission factor = 1.3 g NH<sub>3</sub> per kg DM [Andreae and Merlet, 2001]

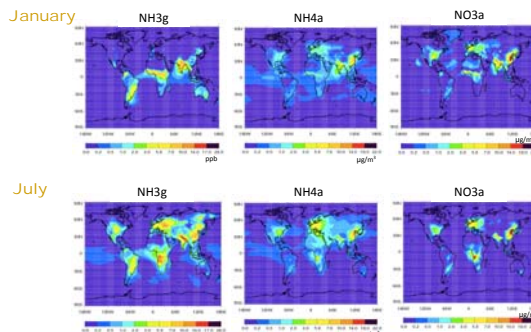

## 3. Results for NH<sub>4</sub>a and NO<sub>3</sub>a simulations

NO<sub>3</sub>a model-observation comparisons with different approaches

Model-observation NO<sub>3</sub>a over CASTNET stations in US for two model approaches: 1. using a thermodynamic equilibrium model (RPMARES) for multiphase chemistry; 2. similar to 1 but adding HNO<sub>3</sub> heterogeneous reaction on dust and sea salt (RPMARES+HetDU+HetSS).

### Surface NH<sub>3</sub>g, NH<sub>4</sub>a, and NO<sub>3</sub>a distributions

- All three tracers concentrated over land regions and follow their emission patterns in both seasons.
- In January, both NH<sub>4</sub>a and NO<sub>3</sub>a spread more widely over Northern Hemisphere (NH) mid-latitudes compared to NH<sub>3</sub>.
- Both NH<sub>3</sub> and NH<sub>4</sub>a were higher in July, but seasonal change of NO<sub>3</sub> varied in regions.

### Compare with station measurements

#### Over single station

GMI captured measured aerosol values and seasonal change better over Castnet stations (North America, NA) than over EMEP stations (Europe, EU).

## 4. Impact of NH<sub>4</sub>a and NO<sub>3</sub>a on surface chemistry field

### January

Change (%) = (CoupleNO<sub>3</sub> – CoupleNoNO<sub>3</sub>) / CoupleNoNO<sub>3</sub>

- HNO<sub>3</sub>g decreased globally in CoupleNO<sub>3</sub> since part of HNO<sub>3</sub>g in CoupleNoNO<sub>3</sub> went into nitrate aerosol.
- Decreased HNO<sub>3</sub>g drove global NO<sub>x</sub> and OH reduction through decreasing its photodissociation.
- Further analysis is needed to understand the response of H<sub>2</sub>O<sub>2</sub> and O<sub>3</sub> to the changes of OH and NO<sub>x</sub>.
- The largest percentage change of NO<sub>x</sub>, OH, H<sub>2</sub>O<sub>2</sub>, and O<sub>3</sub> occurred over Southern tropical and subtropical oceans in January.
- The average global change of O<sub>3</sub> was less than 2%; its largest percentage change occurred over low O<sub>3</sub> regions.

### July

Change (%) = (CoupleNO<sub>3</sub> – CoupleNoNO<sub>3</sub>) / CoupleNoNO<sub>3</sub>

- HNO<sub>3</sub>g was reduced as well.
- The NO<sub>x</sub>, OH, H<sub>2</sub>O<sub>2</sub>, and O<sub>3</sub> were also decreased except in regions with extremely low NO<sub>x</sub> and O<sub>3</sub>.
- The largest percentage change of NO<sub>x</sub>, OH, H<sub>2</sub>O<sub>2</sub>, and O<sub>3</sub> occurred over NH oceans in July.

## 5. Summary

- GMI has a new capability of simulating aerosol ammonium and nitrate.
- Nitrate simulation needs including not only multiple chemistry reactions in a SO<sub>4</sub>-NO<sub>3</sub>a-NH<sub>4</sub>a-H<sub>2</sub>O system, but also the heterogeneous reactions of HNO<sub>3</sub> on dust and sea salt.
- All three tracers (NH<sub>3</sub>g, NH<sub>4</sub>a, and NO<sub>3</sub>a) concentrate over land regions at surface. Concentrations of NH<sub>3</sub>g and NH<sub>4</sub>a are generally larger in summer than in winter.
- Nitrate simulation has a little impact on sulfate simulation, but it results in non-negligible regional changes of some gas tracers including NO<sub>x</sub>, HO<sub>x</sub>, and O<sub>3</sub>.
